Gene therapy. Gene therapy is a cancer treatment that is still in the early stages of research. What genes are. Genes are coded messages that tell cells how to make proteins. Proteins are the molecules that control the way cells behave. Our genes decide what we look like and how our body works.

The rapidly changing field of gene therapy promises a number of innovative treatments for cancer patients. Advances in genetic modification of cancer and immune cells and the use of oncolytic viruses and bacteria have led to numerous clinical trials for cancer therapy, with several progressing to late-stage product development.

Future of Gene Therapy. Gene therapy is quite an innovative technology which is developing and advancing at a rapid pace. The use of gene therapies to create new medical procedures which when used alone or in combination with the currently available treatment (such as chemotherapy) will be able to target cancer and make it a manageable disease.

AAV gene therapy has broad therapeutic implications for a vast array of diseases. Some genetic diseases are caused by mutations in a single gene, while others are a result of mutations in multiple genes, for example, cancer. Additionally, environmental factors, such as smoking and diet, can play a role in diseases.

T-SIGn gene therapy products are “armed” through the addition of genes that cause the tumor to express combinations of biologics including antibodies, cytokines and other immunomodulatory proteins. In effect, the T-SIGn viruses turn the tumor cells into “drug factories” to express combination gene therapy.
